Bellman Ford

```java
/*
Bellman-Ford algorithm for single-source shortest paths with negative edge weights.

Finds shortest paths from a source vertex to all other vertices, even with negative
edge weights. Can detect negative cycles.

Key operations:
- addEdge(u, v, weight): Add directed edge
- shortestPaths(source): Compute shortest paths, returns null if negative cycle detected
- shortestPath(source, target): Get shortest path between two vertices

Time complexity: O(VE)
Space complexity: O(V + E)
*/

Lca

```java
/*
Lowest Common Ancestor (LCA) using Binary Lifting.

Preprocesses a tree to answer LCA queries efficiently.

Key operations:
- addEdge(u, v): Add undirected edge to tree
- build(root): Preprocess tree with given root - O(n log n)
- query(u, v): Find LCA of nodes u and v - O(log n)
- distance(u, v): Find distance between two nodes - O(log n)

Space complexity: O(n log n)

Binary lifting allows us to "jump" up the tree in powers of 2, enabling
efficient LCA queries.

Polygon Area

```java
/*
Shoelace formula (Gauss's area formula) for computing the area of a polygon.

Computes the area of a simple polygon given its vertices in order (clockwise or
counter-clockwise). Works for both convex and concave polygons.

The formula: Area = 1/2 * |sum(x_i * y_(i+1) - x_(i+1) * y_i)|

Time complexity: O(n) where n is the number of vertices.
Space complexity: O(1) additional space.
*/

Priority Queue

priority_queue.java

```java
/*
Generic priority queue (min-heap) with update and remove operations.

Supports:
- push(item): Add item to heap - O(log n)
- pop(): Remove and return minimum item - O(log n)
- peek(): View minimum item without removing - O(1)
- update(old_item, new_item): Update item in heap - O(n)
- remove(item): Remove specific item - O(n)

Standard library alternatives:
- C++: std::priority_queue (basic operations only, no key-based updates/removal)
- Python: heapq module (min-heap only, no key-based updates/removal)
- Java: PriorityQueue class (basic operations only, no key-based updates/removal)

Space complexity: O(n)
*/

Sprague Grundy

```java
/*
Sprague-Grundy theorem implementation for impartial games (finite, acyclic, normal-play).

The Sprague-Grundy theorem states that every impartial game is equivalent to a Nim heap
of size equal to its Grundy number (nimber). For multiple independent games,
XOR the Grundy numbers to determine the combined game value.

API:
- GrundyEngine(moveFunction): makes it easy to plug in any game.
- grundy(state): compute nimber for a state (must be hashable).
- grundyMulti(states): XOR of nimbers for independent subgames.
- isWinningPosition(states): true iff XOR != 0.

Includes implementations for:
- Nim (single heap).
- Subtraction game (allowed moves = {1,3,4}) with period detection.
- Kayles (bowling pins) with splits into subgames via array representation.

Requirements:
- State must be hashable and canonically represented (e.g., sorted arrays).
- moveFunction must not create cycles.
*/

Suffix Array

```java
/*
Suffix Array construction with Longest Common Prefix (LCP) array using Kasai's algorithm.

A suffix array is a sorted array of all suffixes of a string. The LCP array stores the length
of the longest common prefix between consecutive suffixes in the suffix array.

Key operations:
- Constructor: Build suffix array and LCP array for a string
- findPattern(pattern): Find all occurrences of pattern in text

Time complexity: O(n log n) for suffix array, O(n) for LCP array
Space complexity: O(n)
*/

Two Sat

```java
/*
2-SAT solver using Kosaraju's SCC algorithm on implication graph.

2-SAT (Boolean Satisfiability with 2 literals per clause) determines if a Boolean formula
in CNF with at most 2 literals per clause is satisfiable. Uses implication graph where
each variable x has nodes x and not-x, and clause (a OR b) creates edges not-a -> b
and not-b -> a.

Key operations:
- addClause(a, aNeg, b, bNeg): Add clause (a OR b)
- solve(): Returns assignment array if satisfiable, null otherwise

Time complexity: O(n + m) where n is variables and m is clauses
Space complexity: O(n + m)
*/

Union Find

```java
/*
Union-Find (Disjoint Set Union) data structure with path compression and union by rank.

Supports:
- find(x): Find the representative of the set containing x - O(α(n)) amortized
- union(x, y): Merge the sets containing x and y - O(α(n)) amortized
- connected(x, y): Check if x and y are in the same set - O(α(n)) amortized

Space complexity: O(n)

α(n) is the inverse Ackermann function, which is effectively constant for all practical values of n.
*/
